15. SUPPLEMENTARY NOTES

16. ABSTRACT

This report describes the development and evaluation of Method 5B at an oil-fired boiler. Different sampling and analysis techniques for measuring nonsulfuric acid particulate matter were compared and evaluated. Statistical analyses of the results comparing the precision of the different techniques are presented.

SECTION 1

INTRODUCTION

On June 28, 1979, the U.S. Environmental Protection Agency (EPA) issued an advance notice of proposed rulemaking to develop New Source Performance Standards (NSPS) for fossil-fuel-fired industrial steam generators.* Because these sources can emit significant amounts of condensible sulfates that even the best emission reduction systems are unable to control, particulate emissions measured by Method 5, which is capable of collecting condensible matter, could vary widely as a result of fuel sulfur content or process changes. For this reason, the EPA decided that condensible sulfates should not be included in particulate emission standards or measurements. Therefore, the test program undertaken by EPA to support development of the NSPS had two objectives: 1) to obtain background emission data, and 2) to evaluate sampling and analytical parameters designed to minimize collection of condensible sulfate materials from these sources. Background emission data have been collected at several coal-fired facilities and at one oil-fired facility by use of both the proposed Method 5B (to minimize collection of condensible sulfates) and Method 5.

*44 FR 37632.

PEDCo Environmental, Inc., under contract to the Emission Measurement Branch of the EPA, conducted an atmospheric emission test program from February 7 through February 12, 1983, on the exhaust gases of a 400-MW oil-fired utility boiler. Testing was performed in an effort to determine the precision of proposed Method 5B and to evaluate the effect of sampling and analysis parameters on the collection of condensible sulfates.

All samples were collected by use of a four-train (quad) sampling system stationed at a single point in the exit gas stream. A total of 10 quad train tests were performed during the test series. Paired trains in the quad system consisted of similar sampling methods to allow within-run data comparisons as well as comparisons between different sampling methods.

So that method precision could be estimated, most of the samples were collected at Method 5B sampling conditions [filter and probe heated to 160°C (320°F)], designated as M5B.

Other sampling parameter studies have shown generally that 1) a higher sampling temperature can minimize collection of condensible matter, and 2) even a well-designed, well-constructed, and well-operated probe heating system can have cold spots where the gas temperature is lower than the desired monitored probe temperature. Consequently, several of the quad test runs were conducted with the probe heated to 204°C (400°F) in an effort to raise the temperature of any cold spots in the probe to approximately 160°C (320°F), the desired filter temperature. These samples were designated as M5B-P400.

Probe rinse and filter sample fractions collected by Methods 5B and 5B-P400 were subjected to a series of thermogravimetric analyses to assess sample weight loss as a function of heating temperature between ambient conditions and 316°C (600°F).

In addition, several samples (designated M5BW) were collected and analyzed by use of a modified version of Texas Air Control Board (TACB) Method 5W.* The method incorporates deionized water as the sample recovery solvent and a series of titrimetric and gravimetric analyses to measure water-soluble sulfates and subsequently derive the mass of nonwater-soluble sulfate particulate (particulate matter that does not include any water-soluble sulfates). The method was modified by sampling at 160°C (320°F) and measuring the water-soluble sulfates by ion chromatography (IC). These tests were conducted to determine the suitability of this method for fossil-fuel-fired steam generators. Previous studies[1,2] have confirmed the suitability of Method 5W and the IC analysis modification for use on fluid catalytic cracking unit regenerators at petroleum refineries, which also can emit significant amounts of condensible sulfates.

The filterable portion of each sample train was followed by a modified EPA Method 8 impinger train; this permitted analysis of sulfur dioxide (SO_2) and condensible sulfate [as sulfuric acid (H_2SO_4)] that passed through the particulate filter. Flue gas temperature, moisture content, and composition [oxygen (O_2)

*Texas Air Control Board - Laboratory Division. Determination of Particulate in Stack Gases Containing Sulfur Dioxide. December 1979.

and carbon dioxide (CO_2)] were measured in conjunction with the emission tests.

Ms. Jenna Sellers, the host plant's representative, recorded process data and provided assistance on site. Mr. Gary McAlister, the EPA Task Manager, and Mr. Andrew Kasprik, the utility company's representative, provided overall project coordination.

This report documents the activities and results of the test program. Section 2 briefly describes the process and operating conditions during the sampling periods. Section 3 describes the sampling site and the sampling and analytical plan. Section 4 presents the test results, which are then discussed in Section 5. Section 6 outlines quality assurance measures and audit results. The appendices contain computer output and example calculations (Appendix A), field data (Appendix B), analytical data (Appendix C), standard sampling and analytical procedures (Appendix D), calibration procedures and results (Appendix E), a quality assurance summary (Appendix F), a list of project participants (Appendix G), and process data (Appendix H).

SECTION 2

PROCESS OPERATION

The source tested in this program is a 400-MW fossil-fuel-fired utility boiler (designated Unit 2) located in the southeastern United States. The pressurized Foster Wheeler boiler, which was placed in service in 1969, generates steam at 17.9 MPa and 541°C (2590 psig and 1005°C). This unit normally fires a mixture of heavy oil and gas, but it was operated on 100 percent oil during the test program. Fly ash removed by the mechanical dust collectors is automatically reinjected into the furnace. Flue gases are exhausted through a 121-m (397-ft) stack. Typical oil burned in the boiler contains 2.4 percent sulfur and 300 to 400 ppm vanadium. No fuel additives are used at this facility.

Table 2-1 summarizes process conditions during the sampling periods. All tests were conducted at essentially the same boiler load (380-MW), as the load did not vary by more than ±5 percent at any time during the sampling periods. A sudden loss of air flow occurred near the beginning of Run 4, but conditions stabilized in about 10 minutes. The condensate blowdown valve was opened during three runs because of high silica concentrations. None of these relatively minor process variations should affect the within-run data comparisons.

TABLE 2-1. PROCESS DATA SUMMARY

Run No.	Date (1983)	Time, 24-h	Gross load, MW		Stack monitor opacity range, %	Oxygen range at east economizer exit, %	Operation
			Range	Average			
1	2/7	0950-1150	Steady	380	21	0.9-1.0	Normal
2	2/7	1410-1610	Steady	380	22-25	0.8-1.1	Normal
3	2/8	0845-1045	Steady	380	18	0.7-0.8	Normal
4	2/8	1230-1430	Steady	380	22-30	0.6-1.2	[a]
5	2/11	0755-0925	365-378	375	18	0.7	[b]
6	2/11	1050-1220	Steady	380	24	0.4-0.5	CBD open[c]
7	2/11	1330-1500	Steady	380	20	0.6-0.7	CBD open[c]
8	2/11	1620-1650	Steady	375	18	0.8	Normal
9	2/12	0830-1000	Steady	385	20	0.6-0.7	Normal
10	2/12	1200-1330	Steady	385	20	0.6	Normal

[a]At 1250 hours there was a sudden loss of air flow. Conditions returned to normal in approximately 10 minutes.

[b]At 0820 hours the boiler pressure was decreased slightly and the condensate blowdown was opened because of high silica concentrations.

[c]The condensate blowdown was open because of high silica concentrations; boiler at full pressure.

Testing was not conducted on two days because the unit was operating at reduced load (approximately 200-MW) as a result of a malfunctioning condensate pump.

SECTION 3

SAMPLING AND ANALYTICAL PLAN

All samples were collected with a four-train (quad) sample system stationed at a single point in the exit gas stream. The sample methodology was developed and validated in previous studies.[3] The ability of the four trains to sample simultaneously at essentially the same point in the gas stream (Figure 3-1) reduces the effect of spatial and temporal variations in the velocity and particulate profiles on the sampling results. It also permits a statistically significant number of samples to be taken in a short time. Further, because two of the four trains are identical for every run, within-train precision can be determined while the relationship of the different trains is being compared.

3.1 SAMPLE LOCATION

Testing took place in the east duct of Unit 2, as shown in Figures 3-2 and 3-3. Two existing 7.6-cm (3-in.) diameter ports were located 90 degrees apart in each of the horizontal ducts. A new 15-cm (6-in.) I.D. sampling port for the quad-train samples was installed in the side of the east duct above one of the existing smaller ports. All of the ports were located approximately 3 duct diameters downstream from the mechanical dust

collector outlets and 1 duct diameter upstream of a 45-degree bend. Both ducts had an inside diameter of 4.11 m (13.5 ft) surrounded by a 23-cm (9-in.) thick layer of insulation.

3.2 SAMPLE METHODS

The four trains collected flue gas samples simultaneously from a single point in the gas stream. The nozzles of the four-train assembly (Figure 3-1) were positioned 64 cm (25 in.) from the stack wall for each test. The desired sample time was 120 minutes, and readings of stack flue gas and sampling train data were recorded for each train at 10-minute intervals. A single pitot tube and thermocouple located in the four-train nozzle arrangement was used to set isokinetic sample rates for each train. Sample rates were determined by use of programmable calculators. Prior to sampling, the velocity and temperature profile of the general sampling area was established to ensure that all four nozzles could be positioned at points of equal velocity to minimize spatial variations in emissions.

Table 3-1 presents the sample matrix performed during this test series. The particular conditions for each train are described briefly below:

- Method 5B - Designation M5B

  Filterable particulate was collected by use of a probe and filter assembly heated to 160°C (320°F). Acetone was used to rinse all sample train components prior to the filter.

[a]M5B - Probe and filter heated to 160°C.
M5B-P400 - Probe heated to 204°C; filter heated to 160°C.
M5BW - Probe and filter heated to 160°C; water rinse of nozzle, probe, and front filter holder glassware.

- Modified Method 5B - Designation M5B-P400

  Filterable particulate was collected by use of a probe heated to 204°C (400°F) and a filter assembly heated to 160°C (320°F). Acetone was used to rinse all sample train components prior to the filter.

- Method 5BW - Designation M5BW

  Filterable particulate was collected by use of a probe and filter assembly heated to 160°C (320°F). Deionized, distilled water was used to rinse all sample train components prior to the filter.

The purpose of heating the probe to 204°C while keeping the filter at 160°C was to raise the temperature of any cold spots in the probe to 160°C, and thereby minimize the quantity of condensible sulfates collected.

For each train, the probe and filter temperatures were set at the predetermined level and monitored throughout each test by the use of multiterminal digital indicators with the thermocouples located in the middle of each probe and immediately behind the Method 5 filter frits.

The back half of each sample train represented a modified Method 8 with five impingers. An unheated Method 5 filter assembly was inserted between the second and third impingers to preclude any sulfuric acid mist carryover. The contents of each impinger are listed below:

Impinger	Contents - All Runs
1	Empty
2	200 ml 80% IPA
3	100 ml 10% H_2O_2
4	100 ml 10% H_2O_2
5	400 grams silica gel

All the filters were Whatman Reeve Angel 934AH. The filters used in the Method 5 position were heated to 300°C prior to identification and tare weighing.

The flue gas moisture content of each sample train was determined gravimetrically by weighing each impinger before and after every test. In addition, a flue gas grab sample collected during each test was analyzed for oxygen (O_2) and carbon dioxide (CO_2) by use of an Orsat analyzer, as described in Method 3* of the Federal Register.

3.3 SAMPLE ANALYSIS

Table 3-2 presents the analytical matrix followed for this test program.

Thermogravimetric Analysis

Initially, the filter particulate catch was placed in a tared glass weighing dish, desiccated for 24 hours, and weighed to a constant weight.** The probe rinse fraction was transferred to a tared beaker, allowed to evaporate to dryness at ambient temperature and pressure, desiccated for 24 hours, and weighed to a constant weight. Because previous data have shown that samples containing a significant amount of sulfuric acid may not come to a constant weight, each sample received a maximum of three separate weighings. In any case, the lowest weight achieved was reported as the ambient weight.

[a]Thermogravimetric conditioning of probe rinse and filter fractions at indicated temperatures after initial desiccation and ambient weights were obtained. The designation (24) for selected samples indicates a heat period of 24 hours. All other samples were heat-conditioned for 6 hours.

[b]In this procedure, the mass of total water-soluble sulfates in the sample was determined and subtracted from the total sample mass.

Note: All back halves represent a modified Method 8, with analysis for sulfates as sulfuric acid and sulfur dioxide.

After this initial gravimetric analysis at ambient conditions, probe rinse and filter fractions were subjected to the sequence of heat treatments outlined in Table 3-2. The samples were heated in an oven at the specified temperature for either 6 or 24 hours, as indicated. Each sample fraction was cooled and desiccated for 24 hours after removal from the oven and then weighed to the nearest 0.1 mg. Each sample was then desiccated for an additional 3 hours and weighed to the nearest 0.1 mg. The lower weight obtained was reported.

Selected samples received additional heat treatments to evaluate sample stability. For these samples, a heat treatment was repeated at the same time and temperature condition until a stable weight was obtained prior to advancing to the next step of an analytical sequence. For this study, a stable weight was defined as a difference of no more than 5.0 mg or 10 percent of the net sample weight (whichever was greater) between successive treatments at the same conditions. The number of treatments required to achieve a stable weight was recorded for selected sample fractions up to a maximum of three treatments. The lowest weight achieved at a given treatment temperature was reported as the weight for that temperature condition. Filter and acetone blanks were treated in a similar manner as the actual samples.

Water-Soluble Sulfate Analysis

Sample Preparation--

Each sample fraction, including blanks, was handled and analyzed as follows:

Filter - The filter was cut into small pieces and placed in a 125-ml Erlenmeyer flask with a standard taper joint equipped with an air condenser. The shipping container was rinsed into the flask. About 50 ml of distilled water was added and gently refluxed for 6 to 8 hours. The solution was then cooled and diluted to exactly 250 ml with water in a volumetric flask. This was reserved for total soluble sulfate analysis, which is described below.

Probe Rinse - The probe wash was poured into a 250-ml volumetric flask. The sample bottle was rinsed with distilled water and the rinsings were added to the flask. The solution was then diluted to the mark with distilled water (or, if greater than 250 ml, the volume was measured). This solution was reserved for total soluble sulfate analysis, which is described below.

Total Soluble Sulfate Analysis--

A 15-ml aliquot* was drawn from the settled samples (filter and rinse) into separate sample containers with a clean, dry pipet (only solution was transferred, no solids; if necessary, a portion of the sample was centrifuged). The sulfate ion ($SO_4^=$) concentration in each aliquot was determined by ion chromatography (IC). A syringe was used to inject 1 ml of the aliquot into the 100-µl sample loop of the IC, thereby flushing the loop with sample. The conductivity response of the sample was compared with the calibration curve to obtain the $SO_4^=$ concentration in mg/liter. Dilutions were prepared and reanalyzed if the initial response was out of the linear calibration range (i.e., greater than 15 mg/liter). Blank filter and water samples were prepared and analyzed in the same manner as the actual samples.

*The pipet is not rinsed. This is a deviation from normal procedures, but is necessary because the volume removed from the volumetric flask is required in the calculations.

Mass Determination--

Filter and Rinse Solution Preparation - The remaining contents of each volumetric flask (235 ml) were poured into separate tared 250-ml beakers, and the flask was rinsed with distilled water to transfer all particulate matter. The filter solution was in Beaker A and the rinse solution was in Beaker B. This solution was evaporated to approximately 100 ml at 105°C and allowed to cool before proceeding with the next analysis.

Filter and Rinse Solution Analysis - Five drops of phenolphthalein indicator were added to all the tared beakers. Concentrated NH_4OH was then added drop by drop until the solution turned pink. The samples were returned to the oven and evaporated to dryness at 105°C, then cooled in a desiccator and weighed to a constant weight. Results were reported to the nearest 0.1 mg. For this method, "constant weight" means a difference of no more than 0.5 mg or 1 percent of the total weight less beaker and/or filter tare, whichever is greater, between two consecutive weighings, with no less than 6 hours of desiccation time between weighings.

Calculations--

Nomenclature--

FP = weight of particulate* on the filter in Beaker A, mg

PRP = weight of probe rinse particulate* in Beaker B, mg

NWSSP = weight of nonwater-soluble sulfate particulate**, mg

AS_f = weight of ammonium sulfate in filter sample, mg

AS_{pr} = weight of AS in probe rinse sample, mg

V_{evap} = volume of solution evaporated in Beaker A (filter) or Beaker B (probe rinse), ml

C_{SO_4} = concentration of sulfate in filter or probe rinse solution aliquots, mg/liter

*Particulate with H_2SO_4 converted to $(NH_4)_2SO_4$.

**Particulate excluding water-soluble sulfates.

Equations--

$$FP(mg) = \text{gross weight Beaker A} - \text{tare weight Beaker A} - \text{filter tare weight} \quad \text{Eq. 1}$$

$$PRP(mg) = \text{Gross weight Beaker B} - \text{tare weight Beaker B} \quad \text{Eq. 2}$$

$$AS(mg) = C_{SO_4} \text{ (mg/liter)} \times V_{evap} \text{ (ml)} \times \frac{\text{liter}}{1000 \text{ ml}} \times 1.376 \left(\frac{\text{mg AS}}{\text{mg } SO_4}\right) \quad \text{Eq. 3}$$

Mass of Nonwater-Soluble Sulfate Particulate

The sum of the particulate* collected on the filter (FP) and the particulate* collected in the probe rinse (PRP) is equal to the sum of nonwater-soluble sulfate particulate (NWSSP) and ammonium sulfate (AS) in both samples:

$$FP + PRP = NWSSP + AS_f + AS_{pr} \quad \text{Eq. 4}$$

The NWSSP can be found by rearranging the equation and substituting appropriate values determined by use of Equations 1, 2, and 3.

$$NWSSP = FP + PRP - AS_f - AS_{pr} \quad \text{Eq. 5}$$

Sulfuric Acid Mist Analysis

The amount of sulfuric acid that passed through the particulate filter was determined by analyzing the IPA solution recovered in the first two impingers and the backup filter. The volume of the sample solution was recorded, and the pH of the

*Particulate with H_2SO_4 converted to $(NH_4)_2SO_4$.

sample was determined. The sample volume was diluted to 500 ml with 80 percent IPA. A 100-ml aliquot of this solution was pipetted into a 250-ml Erlenmeyer flask with 2 to 3 drops of thorin indicator and titrated to a pink end point by using 0.0100 N barium perchlorate. If the end point color was not correct, the sample was passed through an ion exchange column and retitrated. A blank was titrated for each sample in the same manner.

Sulfur Dioxide Analysis

The hydrogen peroxide sample solution was diluted to 500 ml with deionized, distilled water. A 20-ml aliquot of this solution was pipetted into a 250-Erlenmeyer flask with 80 ml of 100 percent IPA and 2 to 3 drops of thorin indicator. The solution was then titrated to a pink end point by using 0.0100 N barium perchlorate. A blank was titrated in the same manner.

SECTION 4

SUMMARY OF TEST RESULTS

This section summarizes the results of the field sampling program. These results are presented to allow both within-run and between-run data comparisons, with emphasis on the thermogravimetric and water-soluble sulfate test results.

4.1 SAMPLE DATA

Table 4-1 summarizes pertinent sample data. All tests were conducted at a single point where the stack gas velocity profile was relatively flat. The actual probe and filter temperatures, stack temperature, and moisture content represent average values from each individual sample train. Gas composition data (O_2 and CO_2) are given in percent by volume on a dry basis. The isokinetic criteria defined in Reference Method 5* were met in almost every case, as indicated by the values shown in the far right-hand column. The isokinetic sampling rate for Run 3C reflects an adjustment for the post-test leak rate.

The sampling time for Runs 1 through 4 was 120 minutes; however, the sampling time for subsequent runs was shortened to make up for delays incurred during boiler condensate pump malfunctions. As indicated by the sample catch weights listed in

[a] M5B - Probe and filter heated to 160°C.
M5BW - Probe and filter heated to 160°C; water rinse of nozzle, probe, and filter holder.
M5B-P400 - Probe heated to 204°C; filter heated to 160°C.

[b] All desired filter temperatures were 160°C.

[c] Sample volume in dry normal cubic meters (dNm^3) at 20°C and 760 mmHg and in dry standard cubic feet (dscf) at 68°F and 29.92 in.Hg.

[d] The sample volume, moisture content, and isokinetic sampling rate were adjusted to reflect a post-test leak rate of 0.06 cfm.

Table 4-2, an adequate amount of sample was still collected during the 90-minute runs. This was also true for Run 8, which was conducted with a larger nozzle size but stopped after approximately 30 minutes because the isokinetic sampling rate could not be maintained.

4.2 THERMOGRAVIMETRIC ANALYTICAL RESULTS

Table 4-2 presents the thermogravimetric analytical results. The filterable particulate values represent material collected in the sample probe and on the filter for each sample type (M5B, M5B-P400). All weights are reported in milligrams and sample concentrations in milligrams per dry normal cubic meter (mg/dNm^3).

The constant weight criteria described in Method 5* were achieved within two or three weighings during the ambient weighing on approximately 75 percent of the filter and probe rinse samples; however, the remaining samples did not meet the criteria after three weighings.

As previously noted, several selected samples were heat-conditioned at each temperature for either 6 or 24 hours (as indicated in the table) and then reheated at the same conditions until a stable weight was achieved prior to advancing to the next temperature in the analytical sequence. All samples were heated three times at 316°C (600°F). The stable weight criteria, which were defined as a difference of 5.0 mg or less between consecutive similar heat treatments (or 10 percent of the net sample

[a]M5BW samples were analyzed for total water soluble sulfates and particulate mass by modified Texas Air Board procedure described in Section 3 of this report.

[b]Heated for 24 hours, all others heated for 6 hours.

weight, whichever was greater), were achieved in two treatments for selected samples heated at 160°C and 232°C. Several samples heated at 316°C for two treatments appeared to be stable according to the specified criteria, but others had significant weight losses, up to approximately 25 percent (50 mg) in one case. Note that this weight difference occurred between the first and second heat treatments at 316°C, not between two different temperatures. Because of this atypical behavior, all samples were heated a third time at 316°C, even if the stability criteria had been met after two treatments.

Table 4-3 presents the results of individual heatings at 316°C, including the sample weights after the last heating at 232°C as a reference. Approximately 25 percent of the samples did not meet the stability criteria after three heatings at 316°C. In some cases, samples that had met the criteria after two heatings failed to meet it after three heatings. There was no clear advantage to using a 24-h heating interval instead of a 6-h interval, based on the following observation: 14 of the 48 samples heated for 6-h intervals were classified unstable after three heatings at 316°C, and 5 of the 20 samples heated for 24-h intervals also were unstable.

Table 4-4 presents a comparison of total filterable particulate concentrations after heat conditioning at the indicated temperatures for the M5B and M5B-P400 samples. For reporting purposes, the results of similar sample types have been grouped together. The average concentration and standard deviation are

[a]Includes both filter and probe rinse fractions.

[b]Heat conditioning intervals for these samples were 24 hours, all others were 6 hours.

[c]Standard deviation with N-1 weighing for sample data.

[d]Number of data points.

given in mg/dNm³ for all samples of a similar type and temperature. In addition, the number of data points at each temperature condition is shown. Figure 4-1 is a graphical representation of the average data.

Table 4-5 presents the statistical data for each set of grouped runs. Each group represents two runs of the same sample type conducted at the same time, except for run Groups 5, 6, and 9, which represent four similar samples. The M5B data are followed by the M5B-P400 data. Presented for each run group and temperature condition are the mean filterable particulate concentration, the standard deviation with N-1 weighting for sample data, and the relative standard deviation (RSD), which expresses the standard deviation as a percent of the mean concentration.

Table 4-6 summarizes the estimated precision for Methods 5B and 5B-P400 at each conditioning temperature. Method 5B precision data are presented on two bases; the first includes all available data (Runs 1 through 10), and the second includes only data from Runs 3, 4, 8, and 10 to allow a better comparison to within-run M5B-P400 data. The mean filterable concentrations were calculated by averaging grouped run values to weigh two- and four-run groups equally. The mean standard deviations were calculated by averaging standard deviation values for each set of grouped runs (from Table 4-5) to minimize the effect of temporal variation in emissions. In this way, the mean standard deviation of the grouped runs ($\bar{\sigma}$ in Table 4-6) more accurately reflects method precision than does the standard deviation of individual

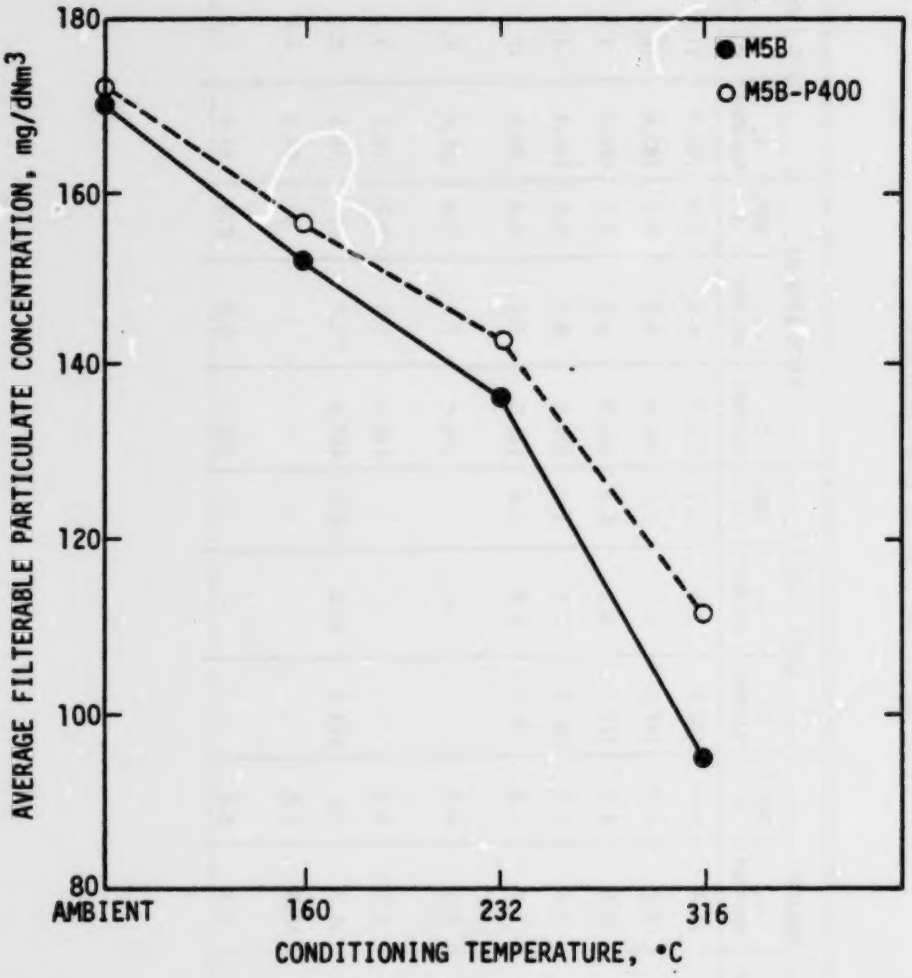

Figure 4-1. Average filterable particulate concentration for similar sample types after conditioning at indicated temperature.

[a] Mean filterable concentration based on grouped run values.

[b] Mean standard deviation of grouped runs ($\frac{\Sigma\sigma_i}{N}$).

[c] Mean relative stanadard deviation (percent) calculated using the mean standard deviation and the mean filterable concentration of grouped runs.

[d] N = number of data points.

run concentrations (σ in Table 4-4). The mean relative standard deviation expresses the mean standard deviation as a percent of the mean concentration. The number of data points included in each calculation is shown for consideration in evaluating the precision estimates.

Table 4-7 presents the relative percent weight loss for the filter samples after conditioning at the indicated temperatures. Percent weight loss was calculated in two ways; 1) by use of the ambient weight as the initial weight basis, and 2) by use of the weight after conditioning at 160°C (320°F) as the initial weight basis. The results of similar sample types have been grouped together. Tables 4-8 and 4-9 present similar data for the probe rinse samples and the total filterable samples, respectively. Figure 4-2 is a graphical representation of the average weight loss data on an ambient weight basis. The graph points out two characteristics of the tabulated data: 1) the most significant weight loss occurred during heating at 316°C (600°F), and 2) the pattern of relative percent weight loss upon heating was similar for all samples.

Because the fuel oil fired during the tests was known to have a relatively high vanadium content (~400 ppm by weight), vanadyl sulfate ($VOSO_4$) was suspected to be one of the components in the particulate matter. A sample of pure vanadyl sulfate was placed in a tared beaker and subjected to a series of heat treatments in the same manner as probe rinse samples. The resultant weight loss data did not follow the same pattern as the samples

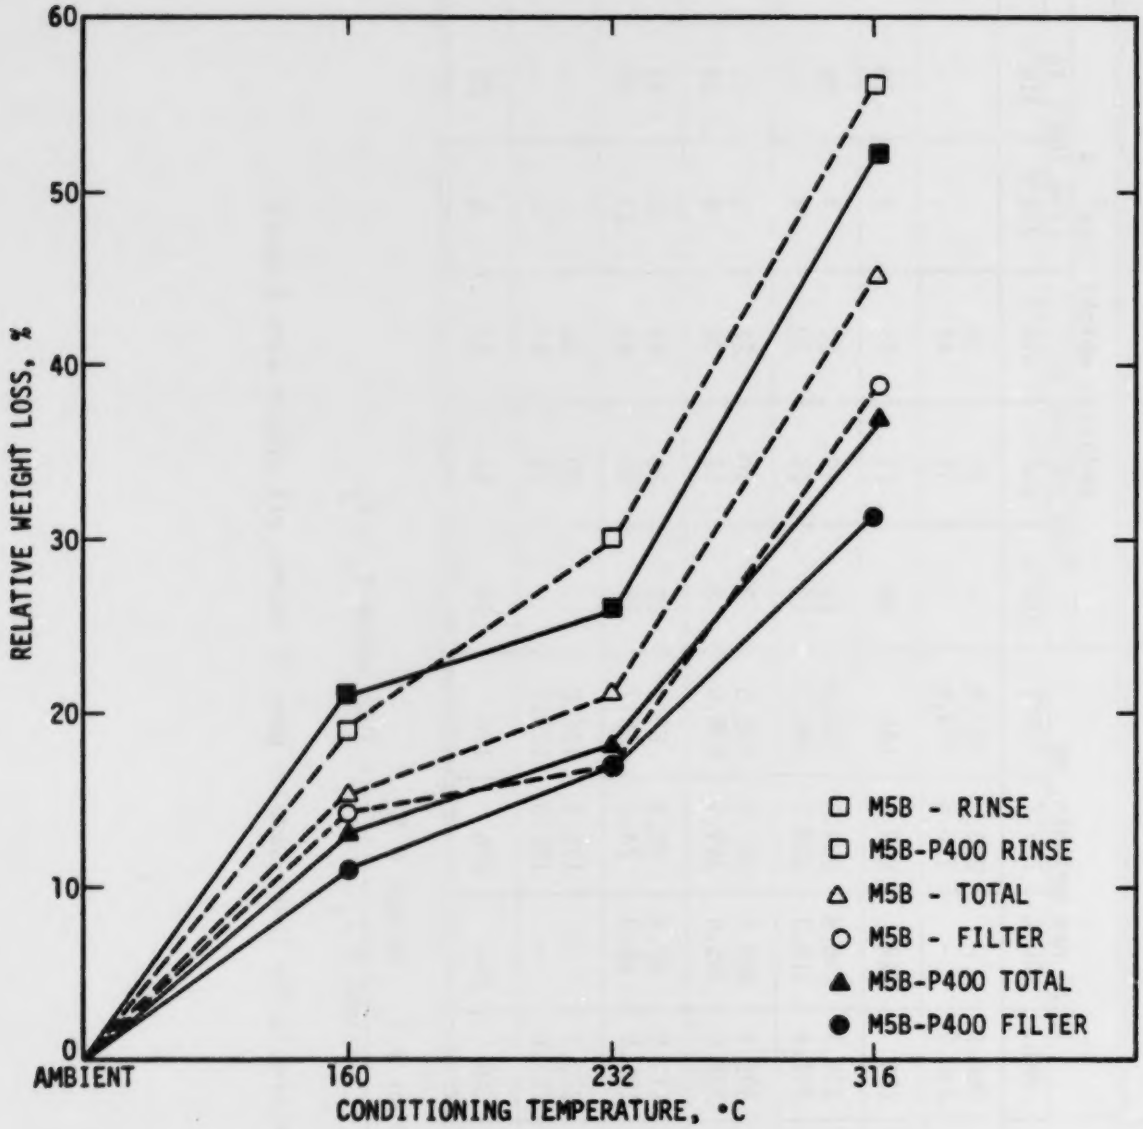

Figure 4-2. Average relative percent weight loss after conditioning at indicated temperatures - ambient weight basis.

in this report, but typified other thermogravimetric analyses that show that the most significant weight loss occurs upon the initial heating at 160°C (320°C).

The filter and probe rinse samples underwent a series of changes in appearance before and during thermogravimetric analysis. Upon recovery in the field, all filters were described as having a green coating. Some filters also had black spots or granular particulate matter. Prior to being desiccated in the laboratory, the filters were described generally as having black specks or black shining spots with a green perimeter. Some filters also had green specks. One filter had a light green glossy surface. During the heatings at 316°C the particulate on the filters turned gradually to a yellow-colored material. The probe rinse samples were basically dark initially, but after heating at 316°C, some of the probe rinse beakers contained some yellow powder along with a black granular particulate matter.

Vanadyl sulfate ($VOSO_4:nH_2O$) is a brillant blue; upon heating at 160°C it turned a dull bluish green; upon heating at 316°C it gradually changed to a greenish yellow.

4.3 WATER-SOLUBLE SULFATE ANALYTICAL DATA

Table 4-10 summarizes the nonwater-soluble sulfate particulate (NWSSP) results of the Method 5BW tests. Since particulate matter cannot be determined gravimetrically in the presence of sulfuric acid because of the inexact amount of water retained by the acid, the method is designed to convert the acid to a nonhygroscopic, nonvolatile product, in this case ammonium sulfate.

TABLE 4-10. SUMMARY OF NONWATER-SOLUBLE SULFATE PARTICULATE RESULTS[a]

7C	33.3	51.7	85.0	63.5					
				Average = 83.3				Average = 95.4	

[a]NWSSP results of the Method 5BW tests using Texas Air Board procedures modified by the use of ion chromatography to measure water-soluble sulfate concentrations.

[b]The samples for Runs 2A and 2B had a higher relative weight loss than similar samples during the heatings at 316°C.

The acid is measured as water-soluble sulfate and converted to ammonium sulfate. The weight of ammonium sulfate formed is subtracted from the total weight of ammonium sulfate and NWSSP (particulate excluding water-soluble sulfates). Results of within-run Method 5B samples are presented for comparison.

As shown in Table 4-10, the average Method 5BW results were lower than the Method 5B results for samples that had been heated to 316°C (600°F). Method precisions were comparable.

The difference in results between the two methods indicates that the Method 5B samples contain water-soluble sulfates that are not easily volatilized by heating at 316°C. It may be possible to identify any cations associated with the residual sulfate by analyzing water extracts of the samples by ion chromatography. Another approach would consist of heating several samples to a higher temperature to determine additional weight loss and stability.

4.4 METHOD 8 ANALYTICAL RESULTS

Table 4-11 presents the results of back-half analyses for sulfates as H_2SO_4 and SO_2. As expected, the H_2SO_4 data show a higher degree of variability than the SO_2 data, which show a high degree of precision. There is no apparent difference in the H_2SO_4 data between the two methods.

[a] Sulfate analysis (as H_2SO_4) per Method 8 (40 CFR 60, Appendix A, July 1, 1981) of IPA impinger contents, back-half filter, and rinse.

[b] SO_2 analysis per Method 8 of peroxide impinger contents and rinse.

SECTION 5

DISCUSSION OF TEST RESULTS

The data both differ and agree with previous studies that characterize condensible sulfate bias of particulate measurements at source emission streams containing sulfur oxides.[2,4,5,6] These studies have shown that sample temperature is a parameter that significantly affects the retention of condensible material in the front half of the standard Method 5 sample train. In this case, condensible matter is defined as probe rinse/filter residue that can be removed by heating. Sulfate species will most likely exist in sources containing sulfur oxides. Water-soluble sulfate can exist in these sources in many different chemical forms. Sulfuric acid (H_2SO_4) is the most common form, but salts of ammonium, sodium, or other cations are also possible. Because exit gas streams from boilers are known to contain sulfur trioxide and sulfur dioxide, sulfuric acid is the most probable form of water-soluble sulfate. Vanadyl sulfate also can be formed during the combustion of high-vanadium residual fuel oils, although the precise effect of this compound on measurements of particulate matter is not completely known.

Data presented in Tables 4-2 and 4-4 show that the use of a higher probe sample temperature did not have a significant effect on the measurement of particulate emissions from this source.

The M5B samples collected at 160°C (320°F) were expected to have a higher particulate catch in the probe rinse than the M5B-P400 samples, which were collected at a probe temperature of 204°C (400°F) and a filter temperature of 160°C; however, this effect was not exhibited. The M5B filterable particulate concentration averaged 170 mg/dNm³ at ambient conditions and compared very well with the M5B-P400 average of 172 mg/dNm³.

Data presented in Table 4-3 show that samples were atypically unstable (according to specified criteria) between heat treatments at the higher temperatures. The variability in weight loss between samples at the same temperature suggests that 316°C may be close to the reaction or decomposition temperature of materials present in the samples.

Effects of analytical temperature are shown graphically in Figure 4-1. The average M5B and M5B-P400 particulate concentrations are similar at each of the three stages of heat conditioning from 160°C (320°F) through 316°C (600°F). The M5B sample concentrations averaged 152, 136, and 94 mg/dNm³ after conditioning at 160°, 232°, and 316°C, respectively. Corresponding results of the M5B-P400 runs at these three temperatures were 156, 143, and 111 mg/dNm³. These data differ from results presented in previous studies in that the most significant sample weight loss normally occurs during the initial heat treatment at 160°C, with subsequent decreasing losses (i.e., the slope of the concentration versus temperature curve becomes flatter). The sample in this study showed a relatively small percent weight loss until they were heated to 316°C, which results in a steeper curve.

An examination of within-run samples (as presented in Table 4-6) shows a closer comparison between the two methods. For Runs 3, 4, 8, and 10, the M5B sample concentrations averaged 155, 145, and 106 mg/dNm³ after conditioning at 160°, 232°, and 316°C, respectively. Corresponding results of the M5B-P400 runs at these three temperatures were 156, 143, and 111 mg/dNm³. The apparent increasing difference between the two methods at higher temperatures is probably related to the increasing instability of the samples.

Weight loss data presented in Tables 4-7 through 4-9 and Figure 4-2 show that both probe rinse and filter samples of each method type lost significant percentages of their ambient weights upon heating, although individual samples varied greatly. The M5B and M5B-P400 filter samples had average weight losses of 39 and 31 percent after thermal treatment at 316°C. This close comparison was expected because the sample filtration temperatures were both 160°C. These percentage weight losses correspond to approximately 65 and 52 mg, respectively.

The M5B and M5B-P400 probe rinse samples had average weight losses of 56 and 52 percent after thermal treatment at 316°C. These percentages correspond to approximately 47 and 37 mg, respectively.

The sample weight loss curve shown in Figure 4-2 begins to flatten out between 160°C and 232°C in a manner similar to previous studies. The abrupt departure from expected behavior at a temperature of 316°C supports the possibility of being close to a reaction temperature of components in the particulate matter.

Statistical data for grouped runs in Tables 4-5 and 4-6 show the precision estimates for Methods 5B and M5B-P400. For a given group of two or four runs, the within-run precision generally worsened between the heat treatments at 232° and 316°C, probably as a result of increased instability of the samples. The mean standard deviation for all 10 M5B run groups was 9.6 mg/dNm³ at ambient conditions, which corresponds to a relative standard deviation (RSD) of 5.6 percent. The four M5B-P400 run groups had a mean standard deviation of 6.0 mg/dNm³ and a corresponding RSD of 3.5 percent at ambient conditions.

The mean standard deviation for the six M5B run groups heated to 160°C was 6.3 mg/dNm³, with a corresponding RSD of 4.1 percent, which indicated a slight improvement over results at ambient conditions. For the three M5B-P400 run groups heated to 160°C, the mean standard deviation and RSD were 5.7 mg/dNm³ and 3.6 percent, respectively.

Precision data for the nine M5B run groups heated to 232°C included a mean standard deviation of 5.7 mg/dNm³ and an RSD of 4.1 percent. For the four M5B-P400 run groups, the average standard deviation and RSD were 7.1 mg/dNm³ and 5.0 percent, respectively.

Precision data for the 10 M5B groups heated to 316°C included a mean standard deviation of 7.2 mg/dNm³ and an RSD of 7.4 percent. For the four M5B-P400 samples, the mean standard deviation and RSD were 4.4 mg/dNm³ and 4.0 percent, respectively.

All of these statistical results indicate a high degree of precision for the majority of samples.

Results of the six M5BW samples and within-run M5B samples presented in Table 4-10 show the disparity between the two methods. The reported nonwater-soluble sulfate particulate (NWSSP) values represent particulate concentrations corrected for water-soluble sulfates determined by ion chromatography (IC). The average NWSSP concentration (83.3 mg/dNm^3) is significantly lower than the average particulate concentration of the within-run M5B samples heated to 316°C (95.4 mg/dNm^3).

A maximum bias of 6 percent (low) could be introduced to the NWSSP value determined by the IC analytical procedure if all of the collected particulate was water-soluble. This is because the aliquot removed for IC analysis is equal to 6 percent of the sample, and the NWSSP result is not corrected for particulate in the aliquot that is water-soluble and nonsulfate. The actual amount of bias is independent of the water-soluble sulfate, but depends on the makeup of the NWSSP. The NWSSP can consist of nonwater-soluble particulate (NWSP) and water-soluble particulate that is not sulfate (WSPNS). Extreme examples of these types of materials would be sand (NWSP) and sodium chloride (WSPNS). If the NWSSP consisted of 75 percent sand and 25 percent salt, the NWSSP results reported from the use of the IC procedure would be biased low by 1.5 percent (6 percent of the WSPNS). For most boiler exhaust gases, the amount of WSPNS in the particulate and the resultant bias to the reported NWSSP should be relatively low.

These NWSSP results indicate that a portion of the water-soluble sulfate initially present in the ambient samples either is not sulfuric acid or it effectively prevents sulfuric acid from being released upon heating to 316°C. It is possible that vanadium present in the fuel oil is responsible for the atypical weight loss results.

As a test for residual sulfates or determination of interfering cations, several of the M5B samples that have been heated to 316°C can be extracted with water for subsequent analysis by IC. Additionally, several of the remaining M5B samples can be heated to 400°C to determine if any additional weight loss is observed.

SECTION 6

QUALITY ASSURANCE

Because the goal of testing is to produce representative emission results, quality assurance is one of the main facets of stack sampling. Quality assurance guidelines provide the detailed procedures and actions necessary for defining and producing acceptable data. Four such documents were used in this test program to ensure the collection of acceptable data and to provide a definition of unacceptable data. These documents are 1) the Source-Specific Test Plan prepared by PEDCo and reviewed by Emission Measurement Branch; 2) the EPA Quality Assurance Handbook Volume III, EPA-600/4-77-027, 3) the PEDCo Environmental Emission Test Quality Assurance Plan, and 4) the PEDCo Environmental Laboratory Quality Assurance Plan. The last two, which are PEDCo's general guideline manuals, define the company's standard operating procedures and are followed by the emission testing groups and the laboratory groups.

Appendix F provides more detail on the quality assurance procedures, such as QA objectives; data reduction; quality control checks; performance and system audits; preventive maintenance; precision, accuracy, and completeness; corrective action; and quality assurance reports to management.

Relative to this specific test program, the following steps were taken to ensure that the testing and analytical procedures produced quality data.

- Calibration of all field sampling equipment. (Appendix E describes calibration guidelines in more detail.)
- Checks on train configuration and calculations.
- Onsite quality assurance checks such as leak checks on the sampling train, pitot tube, and Orsat line, and quality assurance checks of all test equipment prior to use.
- Use of designated analytical equipment and sampling reagents.

Table 6-1 lists the sampling equipment used for quad-train particulate and SO_2 testing as well as the calibration guidelines and limits. In addition to the pre- and post-test calibrations, a field audit was performed on the meter boxes used for the sampling. PEDCo constructed critical orifices for use in this audit. Figures 6-1a through 6-1d show audit runs for each dry gas meter used for testing. Figures 6-2a and 6-2b show thermocouple digital indicator audit runs. Figures 6-3a through 6-3d show thermometer and thermocouple audit data collected during pretest equipment checks.

Between runs, onsite preliminary calculation checks were performed to verify isokinetic sampling rates and to compare moisture contents and other parameters with expected values. These checks were used to ensure that the tests were conducted properly. An example isokinetic calculation sheet is shown in Figure 6-4.

Figure 6-4. Isokinetic calculations.

As a check on the reliability of the method used to analyze particulate samples, sets of filters that had been preweighed in the lab and acetone blanks were submitted for thermogravimetric analysis in a manner similar to the actual samples. Table 6-2 summarizes the results of blank filter and reagent analyses.

Audit solutions prepared by EPA were used to check the analytical procedures and reagents for SO_2 sampling analysis. Table 6-3 presents the results of this analytical audit. Table 6-4 summarizes the results of SO_2 reagent blank analyses. The audit test and blank analyses show that the analytical techniques were good.

Filter and deionized water blanks were analyzed to check the reliability of the analytical methods used to determine nonwater-soluble sulfate particulate. Table 6-5 presents the results of the blank reagent analyses.

The sampling equipment, reagents, and analytical procedures for this test series were in compliance with all necessary guidelines set forth for accurate test results as described in Volume III of the Quality Assurance Handbook.*

UNIT 2 EAST

VOLUME OF DRY GAS SAMPLED AT STANDARD CONDITIONS

VMSTD = (17.647 * VM * Y * (PB + PM / 13.6)) / (TM + 460.)

$$VMSTD = \frac{17.647 * 67.718 * 1.003 * (30.06 + 1.029 / 13.6)}{(67. + 460.)} = 68.519 \text{ DSCF}$$

VOLUME OF WATER VAPOR AT STANDARD CONDITIONS

VWC = .04707 * VLC

VWC = .04707 * 185. = 8.70 SCF

PERCENT MOISTURE IN STACK GAS

BWO = (100. * VWC) / (VMSTD + VWC)

$$BWO = \frac{100. * 8.70}{68.519 + 8.70} = 11.27 \text{ PERCENT}$$

MOLE FRACTION OF DRY STACK GAS

FMD = (100. - BWO) / 100.

$$FMD = \frac{100. - 11.3}{100.} = .887$$

AVERAGE MOLECULAR WEIGHT OF DRY STACK GAS

MD = (PCO2 * .44) + (PO2 * .32) + (PN2 + PCO) * .28

MD = (13.35*44/100) + (2.4*32/100) + ((84.2+ .0) * 28/100 = 30.23

MOLECULAR WEIGHT OF STACK GAS

MWS = MD * (1. - (BWO/100)) + 18. * (BWO/100)

MWS = 30.23* (1. -(11.27/100)) + 18. * (11.27/100) = 28.86

STACK GAS VELOCITY AT STACK CONDITIONS

DELP = SUM. OF THE SQRT(VH * (TS + 460.))

VS = 85.49 * CP * DELP / (SQRT(MWS * PS) * PNTS)

VS = 85.49 * .84 * 273.377 / (SQRT(28.86 * 30.02) * 12. = 55.59 FPS

STACK GAS VOLUMETRIC FLOW AT STACK CONDITIONS

QS = VS * AS * 3600/144

QS = 55.59 * 20612. 3600/144 = 28644928. ACFH

STACK GAS VOLUMETRIC FLOW AT STANDARD CONDITIONS

QSSTD = 17.647 * QS * PS * (1. - (BWO/100)) / (TS + 460.)

$$QSSTD = \frac{17.647 * 28644928. * 30.02 * (1. - (11.27/100))}{(307. + 460.)} = 17546932. \text{ SCFH}$$

PERCENT ISOKINETIC

ISO = (305.58*(TS+460.))*((0.002669*VLC)+(VM*Y*(PB+(PM/13.6))/(TM+460.)))/(TT*VS*PS*DN*DN)

$$ISO = \frac{(305.58*(307.+460.))*((0.002669* 185.)+(67.718*1.003*(30.06+(1.029/13.6))/(67.+460.)))}{120. * 55.59 * 30.02 * .223 * .223} = 103.05 \text{ PERCENT}$$

EXAMPLE PARTICULATE CALCULATIONS TEST NO. ICMSB

UNIT TWO EAST

VOLUME OF DRY GAS SAMPLED AT STANDARD CONDITIONS

VMSTD = (17.647 * VM * Y * (PB + PM / 13.6)) / (TM + 460.)

$$VMSTD = \frac{17.647 * 64.960 * .983 * (30.06 + 1.032 / 13.6)}{(68. + 460.)} = 64.260 \text{ DSCF}$$

VOLUME OF WATER VAPOR AT STANDARD CONDITIONS

VWC = .04707 * VLC

VWC = .04707 * 177. = 8.33 SCF

PERCENT MOISTURE IN STACK GAS

BWO = (100. * VWC) / (VMSTD + VWC)

$$BWO = \frac{100. * 8.33}{64.260 + 8.33} = 11.48 \text{ PERCENT}$$

MOLE FRACTION OF DRY STACK GAS

FMD = (100. - BWO) / 100.

$$FMD = \frac{100. - 11.5}{100.} = .885$$

AVERAGE MOLECULAR WEIGHT OF DRY STACK GAS

MD = (PCO2 * .44) + (PO2 * .32) + (PN2 + PCO) * .28

MD = (13.35*44/100) + (2.4*32/100) + ((84.2+ .0) * 28/100 = 30.23

MOLECULAR WEIGHT OF STACK GAS

MWS = MD * (1. - (BWO/100)) + 18. * (BWO/100)

MWS = 30.23* (1. -(11.48/100)) + 18. * (11.48/100) = 28.83

STACK GAS VELOCITY AT STACK CONDITIONS

DELP = SUM. OF THE SQRT(VH * (TS + 460.))

VS = 85.49 * CP * DELP / (SQRT(MWS * PS) * PNTS)

VS = 85.49 * .84 * 273.377 / (SQRT(28.83 * 30.02) * 12. = 55.61 FPS

STACK GAS VOLUMETRIC FLOW AT STACK CONDITIONS

QS = VS * AS * 3600/144

QS = 55.61 * 20612. 3600/144 = 28657476. ACFH

STACK GAS VOLUMETRIC FLOW AT STANDARD CONDITIONS

QSSTD = 17.647 * QS * PS * (1. - (BWO/100)) / (TS + 460.)

$$QSSTD = \frac{17.647 * 28657476. * 30.02 * (1. - (11.48/100))}{(307. + 460.)} = 17513744. \text{ SCFH}$$

PERCENT ISOKINETIC

ISO = (305.58*(TS+460.))*((0.002669*VLC)+(VM*Y*(PB+(PM/13.6))/(TM+460.)))/(TT*VS*PS*DN*ON)

$$ISO = \frac{(305.58*(307.+460.))*((0.002669* 177.)+(64.960* .983*(30.06+(1.032/13.6))/(68.+460.)))}{120. * 55.61 * 30.02 * .221 * .221} = 98.59 \text{ PERCENT}$$

PARTICULATE LOADING -- EPA METHOD 5 (AT STANDARD CONDITIONS)

VOLUME OF DRY GAS SAMPLED AT STANDARD CONDITIONS

VMSTD = (17.647 * VM * Y * (PB + PM / 13.6)) / (TM + 460.)

$$VMSTD = \frac{17.647 * 69.653 * 1.003 * (30.07 + 1.066 / 13.6)}{(71. + 460.)} = 70.036 \text{ DSCF}$$

VOLUME OF WATER VAPOR AT STANDARD CONDITIONS

VWC = .04707 * VLC

VWC = .04707 * 177. = 8.32 SCF

PERCENT MOISTURE IN STACK GAS

BWO = (100. * VWC) / (VMSTD + VWC)

$$BWO = \frac{100. * 8.32}{70.036 + 8.32} = 10.62 \text{ PERCENT}$$

MOLE FRACTION OF DRY STACK GAS

FMD = (100. - BWO) / 100.

$$FMD = \frac{100. - 10.6}{100.} = .894$$

AVERAGE MOLECULAR WEIGHT OF DRY STACK GAS

MD = (PCO2 * .44) + (PO2 * .32) + (PN2 + PCO) * .28

MD = (13.60*44/100) + (2.9*32/100) + ((83.4+ .0) * 28/100 = 30.29

MOLECULAR WEIGHT OF STACK GAS

MWS = MD * (1. - (BWO/100)) + 18. * (BWO/100)

MWS = 30.29* (1. -(10.62/100)) + 18. * (10.62/100) = 28.99

STACK GAS VELOCITY AT STACK CONDITIONS

DELP = SUM. OF THE SQRT(VH * (TS + 460.))

VS = 85.49 * CP * DELP / (SQRT(MWS * PS) * PNTS)

VS = 85.49 * .84 * 277.170 / (SQRT(28.99 * 30.03) * 12. = 56.22 FPS

STACK GAS VOLUMETRIC FLOW AT STACK CONDITIONS

QS = VS * AS * 3600/144

QS = 56.22 * 20612. 3600/144 = 28970800. ACFH

STACK GAS VOLUMETRIC FLOW AT STANDARD CONDITIONS

QSSTD = 17.647 * QS * PS * (1. - (BWO/100)) / (TS + 460.)

$$QSSTD = \frac{17.647 * 28970800. * 30.03 * (1. - (10.62/100))}{(310. + 460.)} = 17828276. \text{ SCFH}$$

PERCENT ISOKINETIC

ISO = (305.58*(TS+460.))*((0.002669*VLC)+(VH*Y*(PB+(PM/13.6))/(TM+460.)))/(TT*VS*PS*DN*DN)

$$ISO = \frac{(305.58*(310.+460.))*((0.002669* 177.)+(69.653*1.003*(30.07+(1.066/13.6))/(71.+460.)))}{120. * 56.22 * 30.03 * .224 * .224} = 102.74 \text{ PERCENT}$$

PARTICULATE LOADING -- EPA METHOD 5 (AT STANDARD CONDITIONS)

CS = 0.001 * MN * 15.43 / VMSTD

CS = 0.001 * 389.7 * 15.43 / 70.036 = .0859 GR/DSCF

EXAMPLE PARTICULATE CALCULATIONS TEST NO.2DW5BW

UNIT TWO EAST

VOLUME OF DRY GAS SAMPLED AT STANDARD CONDITIONS

VMSTD = (17.647 * VM * Y * (PB + PM / 13.6)) / (TM + 460.)

$$VMSTD = \frac{17.647 * 58.450 * 1.030 * (30.07 + .895 / 13.6)}{(66. + 460.)} = 60.883 \text{ DSCF}$$

VOLUME OF WATER VAPOR AT STANDARD CONDITIONS

VWC = .04707 * VLC

VWC = .04707 * 160. = 7.53 SCF

PERCENT MOISTURE IN STACK GAS

BWO = (100. * VWC) / (VMSTD + VWC)

$$BWO = \frac{100. * 7.53}{60.883 + 7.53} = 11.01 \text{ PERCENT}$$

MOLE FRACTION OF DRY STACK GAS

FMD = (100. - BWO) / 100.

$$FMD = \frac{100. - 11.0}{100.} = .890$$

AVERAGE MOLECULAR WEIGHT OF DRY STACK GAS

MD = (PCO2 * .44) + (PO2 * .32) + (PN2 + PCO) * .28

MD = (13.60*44/100) + (2.9*32/100) + ((83.4+ .0) * 28/100 = 30.29

MOLECULAR WEIGHT OF STACK GAS

MWS = MD * (1. - (BWO/100)) + 18. * (BWO/100)

MWS = 30.29* (1. -(11.01/100)) + 18. * (11.01/100) = 28.94

STACK GAS VELOCITY AT STACK CONDITIONS

DELP = SUM. OF THE SQRT(VH * (TS + 460.))

VS = 85.49 * CP * DELP / (SQRT(MWS * PS) * PNTS)

VS = 85.49 * .84 * 277.170 / (SQRT(28.94 * 30.03) * 12. = 56.27 FPS

STACK GAS VOLUMETRIC FLOW AT STACK CONDITIONS

QS = VS * AS * 3600/144

QS = 56.27 * 20612. 3600/144 = 28994660. ACFH

STACK GAS VOLUMETRIC FLOW AT STANDARD CONDITIONS

QSSTD = 17.647 * QS * PS * (1. - (BWO/100)) / (TS + 460.)

$$QSSTD = \frac{17.647 * 28994660. * 30.03 * (1. - (11.01/100))}{(310. + 460.)} = 17765544. \text{ SCFH}$$

PERCENT ISOKINETIC

ISO = (305.58*(TS+460.))*((0.002669*VLC)+(VM*Y*(PB+(PM/13.6))/(TM+460.)))/(TT*VS*PS*DN*DN)

$$ISO = \frac{(305.58*(310.+460.))*((0.002669* 160.)+(58.450*1.030*(30.07+(.895/13.6))/(66.+460.)))}{120. * 56.27 * 30.03 * .210 * .210} = 101.98 \text{ PERCENT}$$

PARTICULATE LOADING -- EPA METHOD 5 (AT STANDARD CONDITIONS)

EXAMPLE PARTICULATE CALCULATIONS TEST NO.10DMSP

UNIT TWO EAST

VOLUME OF DRY GAS SAMPLED AT STANDARD CONDITIONS

VMSTD = (17.647 * VM * Y * (PB + PM / 13.6)) / (TM + 460.)

$$VMSTD = \frac{17.647 * 45.578 * 1.030 * (30.27 + .958 / 13.6)}{(69. + 460.)} = 47.525 \text{ DSCF}$$

VOLUME OF WATER VAPOR AT STANDARD CONDITIONS

VWC = .04707 * VLC

VWC = .04707 * 138. = 6.47 SCF

PERCENT MOISTURE IN STACK GAS

BWO = (100. * VWC) / (VMSTD + VWC)

$$BWO = \frac{100. * 6.47}{47.525 + 6.47} = 11.99 \text{ PERCENT}$$

MOLE FRACTION OF DRY STACK GAS

FMD = (100. - BWO) / 100.

$$FMD = \frac{100. - 12.0}{100.} = .880$$

AVERAGE MOLECULAR WEIGHT OF DRY STACK GAS

MD = (PCO2 * .44) + (PO2 * .32) + (PN2 + PCO) * .28

MD = (13.00*44/100) + (3.0*32/100) + ((84.0+ .0) * 28/100 = 30.20

MOLECULAR WEIGHT OF STACK GAS

MWS = MD * (1. - (BWO/100)) + 18. * (BWO/100)

MWS = 30.20* (1. -(11.99/100)) + 18. * (11.99/100) = 28.74

STACK GAS VELOCITY AT STACK CONDITIONS

DELP = SUM. OF THE SQRT(VH * (TS + 460.))

VS = 85.49 * CP * DELP / (SQRT(MWS * PS) * PNTS)

VS = 85.49 * .84 * 219.484 / (SQRT(28.74 * 30.24) * 9. = 59.41 FPS

STACK GAS VOLUMETRIC FLOW AT STACK CONDITIONS

QS = VS * AS * 3600/144

QS = 59.41 * 20612. 3600/144 = 30612136. ACFH

STACK GAS VOLUMETRIC FLOW AT STANDARD CONDITIONS

QSSTD = 17.647 * QS * PS * (1. - (BWO/100)) / (TS + 460.)

$$QSSTD = \frac{17.647 * 30612136. * 30.24 * (1. - (11.99/100))}{(326. + 460.)} = 18282604. \text{ SCFH}$$

PERCENT ISOKINETIC

ISO = (305.58*(TS+460.))*((0.002669*VLC)+(VM*Y*(PB+(PM/13.6))/(TM+460.)))/(TT*VS*PS*DN*DN)

$$ISO = \frac{(305.58*(326.+460.))*((0.002669* 138.)+(45.578*1.030*(30.27+(.958/13.6))/(69.+460.)))}{90. * 59.41 * 30.24 * .210 * .210} = 103.14 \text{ PERCENT}$$

PARTICULATE LOADING -- EPA METHOD 5 (AT STANDARD CONDITIONS)

CS = 0.001 * MN * 15.43 / VMSTD

CS = 0.001 * 213.8 * 15.43 / 47.525 = .0694 GR/DSCF

APPENDIX D

SAMPLING AND ANALYTICAL PROCEDURES

SAMPLING AND ANALYTICAL PROCEDURES

A four-train (quad) sampling system was used in this test program. This system allowed four samples to be collected simultaneously at essentially the same point in the gas stream. Each individual sampling train consisted of a Method 5* fronthalf and a Method 8* backhalf. Method 5 sampling procedures were used for all tests, except as noted.

SAMPLING APPARATUS

The sampling train(s) used in these tests met design specifications established by the Federal EPA and was assembled by PEDCo personnel. Each train, set up as shown in Figure D-1, consisted of:

Nozzle - Stainless steel (316) with sharp, tapered leading edge and accurately measured round opening.

Probe - Borosilicate glass with a heating system capable of maintaining the desired gas temperature at the exit end during sampling.

Filter Holder - Pyrex glass with heating system capable of maintaining a filter temperature at desired levels.

Impingers - Five impingers connected in series with glass ball joints. The first, fourth, and fifth impingers were of the Greenburg-Smith design, modified by replacing the tip with a 1/2 inch I.D. glass tube extending to 1/2 inch from the bottom of the flask.

---

*40 CFR 60, Appendix A, July 1981.

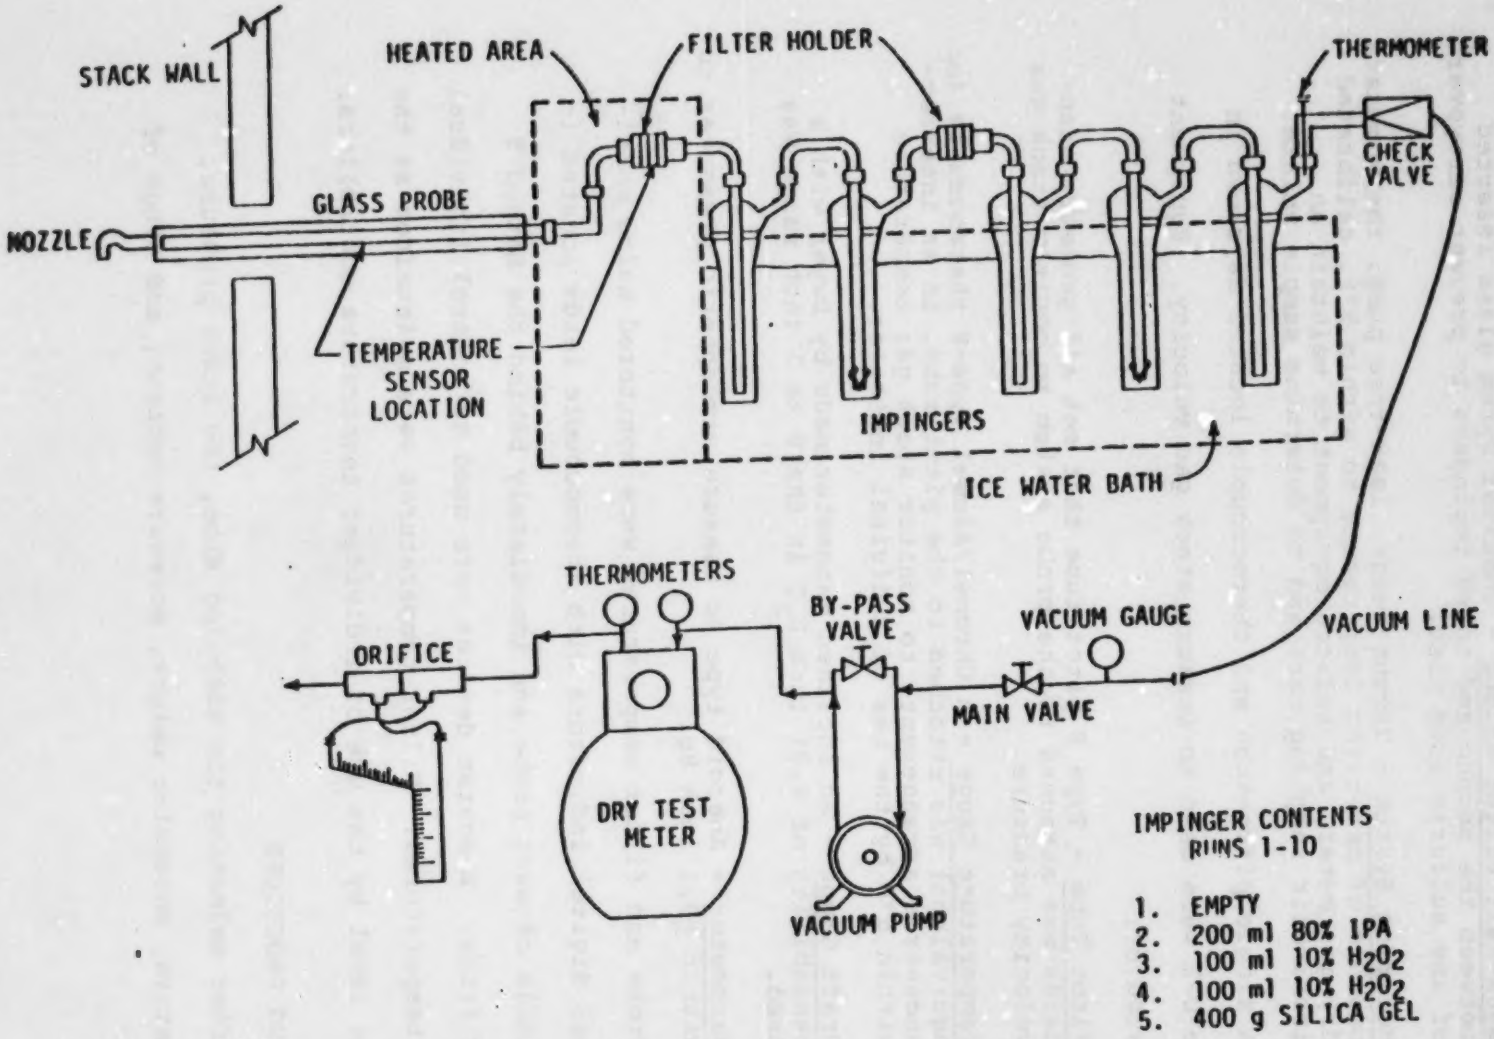

Figure D-1. Methods 5 and 8 sampling train schematic.

Back-Half Filter Holder - Unheated Pyrex glass inserted between the second and third impingers to prevent carryover of any sulfuric acid mist.

Metering System - Vacuum guage, leak-free pump, thermometers capable of measuring temperature to within 5°F, calibrated dry gas meter, and related equipment to maintain an isokinetic sampling rate and to determine sample volume.

A single pitot-tube and thermocouple located as shown in Figure D-2 were used to measure stack gas velocity. Equipment consisted of:

Pitot Tube - Type S pitot tube that met all geometry standards was attached to the probe system to monitor stack gas velocity pressure.

Temperature Gauge - A Chromel/Alumel Type-K thermocouple (or equivalent) was attached to the pitot tube, in an interference-free arrangement, to monitor stack gas temperature within 5°F by the use of a digital indicator.

Draft Gauge - An inclined manometer made by Dwyer with a readability of 0.01 inch H_2O in the 0 to 1 inch range was used.

Barometer - Aneroid type to measure atmospheric pressures to within $\pm$0.1 inch Hg.

Probe and filter temperatures were monitored using multi-terminal digital indicators with thermocouple leads located in the middle of each probe and immediately behind the Method 5 filter frits. Rheostat devices were used to control individual probe temperatures. Filter temperatures were maintained at the desired level by the use of individual temperature controllers.

SAMPLING PROCEDURE

After selecting the sampling site, the stack pressure, temperature, molecular weight, moisture content, and range of

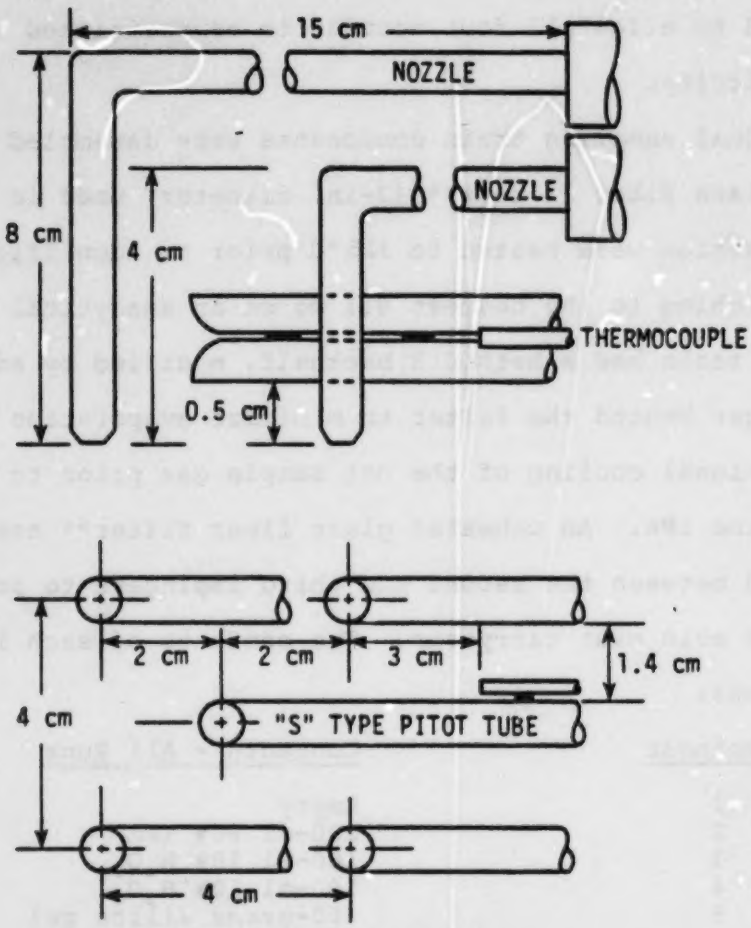

Figure D-2. Four-train sampling system showing nozzle, pitot tube, and thermocouple position.

velocity head in the general sampling area were measured according to procedures described in the Federal Register.* A single sampling point located approximately 0.6 m from the stack wall was selected to allow all four nozzles to be positioned at points of equal velocity.

Individual sampling train components were assembled and labeled. Glass fiber filters** (3-in. diameter) used in the Method 5 position were heated to 315 °C prior to identification and tare weighing to the nearest 0.1 mg on an analytical balance. Each sample train had a Method 8 backhalf, modified by adding a fifth impinger behind the filter to minimize evaporation loss of IPA by additional cooling of the hot sample gas prior to its contacting the IPA. An unheated glass fiber filter** assembly was inserted between the second and third impingers to preclude any sulfuric acid mist carryover. The contents of each impinger was as follows:

Impinger	Contents - All Runs
1	Empty
2	200-ml 80% IPA
3	100-ml 10% H_2O_2
4	100-ml 10% H_2O_2
5	400-grams silica gel

The sampling train subassemblies (probes, filter holders, impingers) were transported to the test site and assembled in the quad train configuration as shown in Figure D-3. The sampling trains were leak checked at the sampling site prior to each test

---

*40 CFR 60, Appendix A, Reference Methods 2, 3, and 4, July 1, 1981.

**Whatman RA 934AH.

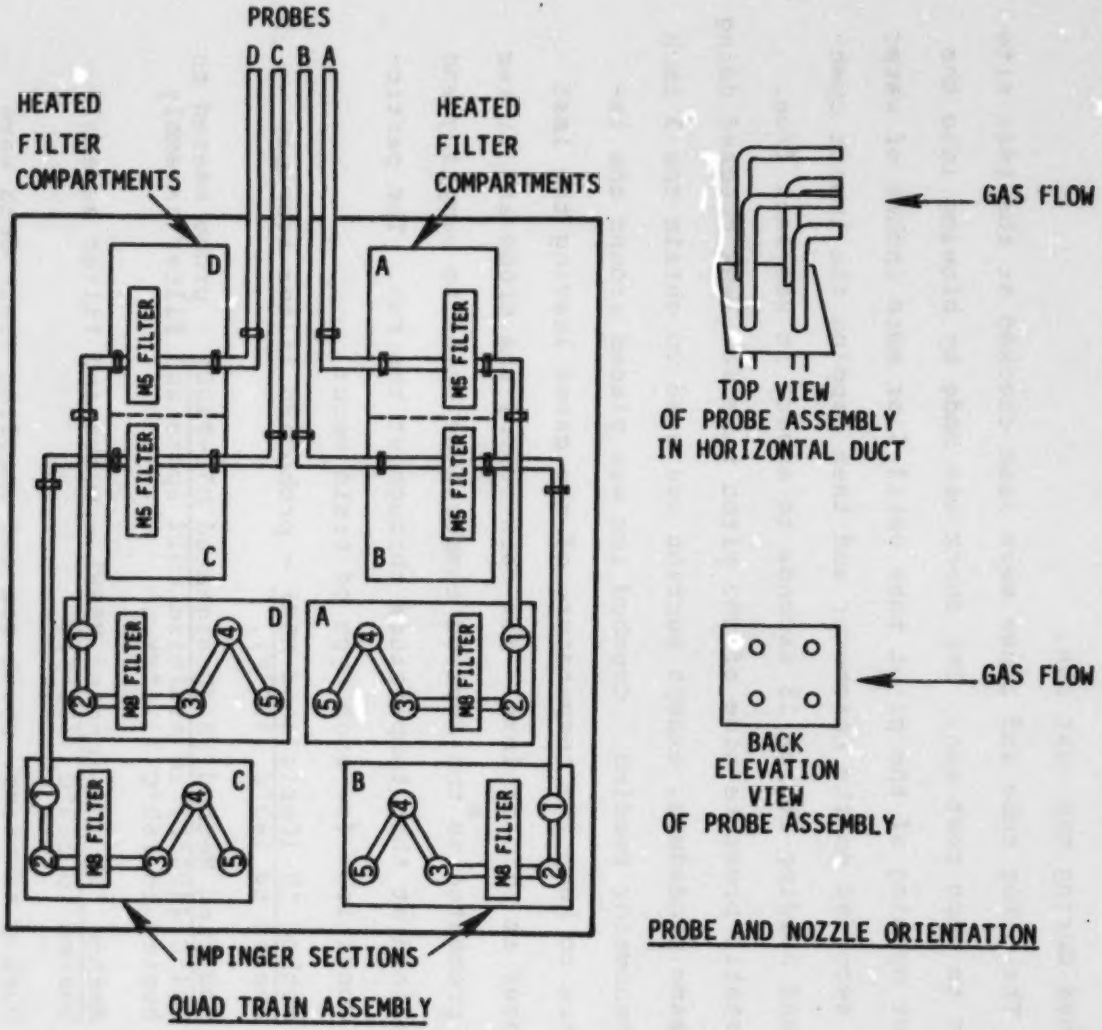

Figure D-3. Quad train configuration.

run by plugging the inlet to the nozzle and pulling a 15 inch Hg vacuum, and at the conclusion of the test by plugging the inlet to the nozzle and pulling a vacuum equal to the highest vacuum reached during the test run.

The pitot tube and lines were leak checked at the test site prior to each test run. The check was made by blowing into the impact opening of the pitot tube until 3 or more inches of water were recorded on the manometer and then capping the impact opening and holding it for 15 seconds to assure it was leak free. The static pressure side of the pitot tube was leak checked using the same procedure, except suction was used to obtain the 3 inch H_2O manometer reading. Crushed ice was placed around the impingers to keep the temperature of the gases leaving the last impinger at 20°C or less. For each train, the probe and filter were preheated to the desired temperature prior to sampling and maintained at that temperature throughout the run. The particular conditions for each type of train were:

Method 5B (Designated M5B) - probe and filter assembly heated to 160°C (320°F).

Modified Method 5B (Designated M5B-P400) - probe heated to 204°C (400°F) to minimize cold spots and filter assembly heated to 160°C (320°F).

Method 5BW (Designated M5BW) - probe and filter assembly heated to 160°C (320°F).

During sampling, stack gas and sampling train data were recorded at 10-minute intervals and when significant changes in stack flow conditions occurred. Isokinetic sampling rates were

set throughout the sampling period with the aid of a programmable calculator. All sampling data were recorded on the Particulate Field Data Sheet.

SAMPLE RECOVERY

The components of the quad train sample system were labeled and disassembled at the stack for transport to the sample clean-up/setup area. The filter and probe assemblies were recovered as follows:

- All filters were carefully removed from the filter holder and placed in a petri dish. These filters were sealed and labeled for shipment.
- For Methods 5B and M5B-P400, loose particulate from all sample exposed surfaces prior to the filter and acetone washings were placed in a polyethylene container, sealed, and labeled. For Method 5BW, deionized, distilled water was used for the probe rinse. Particulate was removed from the nozzle and probe with a nylon brush. The liquid level was marked after each container was sealed.

The impinger section of each sample train (modified Method 8) was removed from its ice bath and purged with ambient air for 15 minutes before recovering the contents. The long glass connector between the front filter holder and first impinger was not purged.

The contents were recovered as follows:

- After gravimetric weighing, the contents of the first and second impingers (condensate and 80 percent IPA) were placed in a polyethylene container. The impingers and connecting glassware between the front and backhalf filter were rinsed with 80 percent IPA and the rinse was added to the container along with the backhalf filter. The containers were then sealed, labeled, and the liquid level marked.

- After gravimetric weighing, the contents of the third and fourth impingers (10 percent H_2O_2) were placed in a polyethlyene container. The impingers and connecting glassware were rinsed with deionized, distilled water and the rinse was added to the container. The containers were then sealed, labeled, and the liquid level marked.

- The color of the silica gel was noted on the sample recovery sheet and the net weight gain determined gravimetrically.

Blank samples were taken for each new batch (or a minimum of two) of the following reagents: acetone; deionized, distilled water; 80 percent IPA; 10 percent H_2O_2; and a filter. In addition, each probe was rinsed prior to initial use with either water or acetone (depending on method type), and these rinses were retained for probe rinse blank analysis.

SAMPLE LABELING

The sample label identifies the test run number, sample train, and each component of the individual train. The run numbers are consecutive from 1 to 10. Since each run consists of four single trains, each train was identified by a letter A, B, C, or D.

The last item of the label identifies the sample method and the component of the recovered sample. For example, identification No. 1C M5B-IPA indicates Test Run 1, Sample Train C, Method 5B sample method at 160°C (320°F) and the IPA impinger contents and rinse. Another example is 4A M5B-P400-Probe indicating Test Run 4, Sample Train A, Modified Method 5B sample method (filter at 160°C and probe at 204°C), and the probe rinse fraction.

SAMPLE RECEIPT AND CHAIN OF CUSTODY

Every sample entering the lab for analysis was assigned a unique alphanumeric identity on a Sample Receipt and Record Sheet (log). In the sample log-in book, this number was correlated with sample identification label and with the number of the analysis requisition form. A copy of the analysis requisition was kept with the samples and later with the raw data.

The samples remained in a locked sample storage room until removed for analysis. Transfer was documented on a Sample Control Record which is maintained by the sample custodian. The Sample Control Record documents all custody changes which occur in the laboratory and each procedure performed on the sample.

Release of samples requires notation of the Sample Control Record and verification of information and sample container condition. If the sample is to be transferred between two persons (i.e., two analysts), the transfer must take place through the sample custodian. In other words, the sample will be returned to the sample custodian and reissued.

SAMPLE ANALYSIS

Particulate Analysis

Initially, the filter particulate catch was placed in a tared glass weighing dish, desiccated for 24 hours, and weighed to the nearest 0.1 mg until a constant weight was achieved. The probe rinse fraction was transferred to a tared beaker and evaporated to dryness at ambient temperature and pressure, desiccated

for 24 hours, and weighed to the nearest 0.1 mg until a constant weight was achieved.

For this study a constant weight was defined as a difference of no more than 0.5 mg or 1 percent of the net weight, whichever was greater, between successive weighings, with at least 6 hours of desiccation between weighings. This is the same definition as for Method 5. Because previous data have shown that samples containing a significant amount of sulfuric acid may not come to a constant weight, each sample received a maximum of three separate weighings. In any case, the lowest weight achieved was reported as the ambient weight.

After this initial gravimetric analysis at ambient conditions, probe rinse and filter fractions were subjected to the sequence of heat treatments as outlined in the analytical matrix (Table 3-2). The samples were heated in an oven at the specified temperature for either 6 or 24 hours as indicated. Each sample fraction was cooled and desiccated for 24 hours after removal from the oven and weighed to the nearest 0.1 mg. Each sample was desiccated from an additional 3 hours and weighed to the nearest 0.1 mg. The lower weight achieved was reported.

Selected samples received additional heat treatments in order to evaluate sample stability. Prior to advancing to the next step of an analytical sequence, a heat treatment was repeated at the same time and temperature condition until a stable weight was obtained for these selected samples. For this study a stable weight was defined as a difference of no more than 5.0 mg

or 10 percent of the net sample weight, whichever was greater, between successive treatments at the same conditions. The number of treatments required to achieve a stable weight was recorded for each sample fraction up to a maximum of three treatments. The lowest weight achieved at a given treatment temperature was reported as the weight for that temperature condition. Filter and acetone blanks were treated in a similar manner as the samples.

Water-Soluble Sulfate Determination

Each sample fraction plus blanks were handled and analyzed as follows:

- Filter - The filter was cut into small pieces and placed in a 125-ml Erlenmeyer flask with a standard type joint equipped with an air condenser. The contents of the shipping container were rinsed into the flask. About 50 ml of distilled water was added and the contents gently refluxed for 6 to 8 hours. The solution was then cooled and diluted with water to exactly 250 ml in a volumetric flask. This solution was reserved for total soluble sulfate analysis, which is described below.

- Probe Rinse - The probe wash was poured into a 250 ml volumetric flask. The sample bottle was rinsed with distilled water and the rinsings were added to the flask. The solution was then diluted to the mark with distilled water (or, if greater than 250 ml, the volume was measured). This solution was reserved for total soluble sulfate analysis, which is described below.

Total Soluble Sulfate--

A 15-ml aliquot* was drawn from the settled samples (filter and rinse) into separate sample containers with a clean, dry pipet (only solution was transferred--no solid; if necessary, a portion of the sample was centrifuged). The sulfate ion ($SO_4^=$)

*The pipet is not rinsed. This deviation from normal procedures is necessary because the volume removed from the volumetric flask is required in the calculations.

concentration in each aliquot was determined by ion chromatography (IC). A syringe was used to inject 1 ml of the aliquot into the 100-µl sample loop of the IC, thereby flushing the loop with sample. The conductivity response of the sample was compared with the calibration curve to obtain $SO_4^=$ concentration in mg/liter. Dilutions were prepared and reanalyzed if the initial response was out of the linear calibration range (i.e., greater than 15 mg/liter). Blank filter and water samples were prepared and analyzed in the same manner as the actual samples.

Mass Determination--

Filter and Rinse Solution Preparation - The remaining contents of each volumetric flask (235 ml) were poured into separate tared 250-ml beakers, and the flask was rinsed with distilled water to transfer all particulate matter. The filter solution was in Beaker A and the rinse solution was in Beaker B. These solutions were evaporated to approximately 100 ml at 105°C and allowed to cool before the next analysis was made.

Filter and Rinse Solution Analysis - Five drops of phenolphthalein indicator were added to all the tared beakers. Concentrated NH_4OH was then added drop by drop until the solution turned pink. The samples were returned to the oven and evaporated to dryness at 105°C, then cooled in a desiccator and weighed to a constant weight. Results were reported to the nearest 0.1 mg. For this method, "constant weight" means a difference of no more than 0.5 mg or 1 percent of the total weight less beaker and/or filter tare, whichever is greater, between two consecutive weighings, with no less than 6 hours of desiccation time between weighings.

Calculations--

Nomenclature--

FP = weight of particulate* on the filter in Beaker A, mg

PRP = weight of probe rinse particulate* in Beaker B, mg

*Particulate with H2SO4 converted to (NH4)2SO4.

NWSSP = weight of nonwater-soluble sulfate particulate*, mg

AS_f = weight of ammonium sulfate in filter sample, mg

AS_{pr} = weight of AS in probe rinse sample, mg

V_{evap} = volume of solution evaporated in Beaker A (filter) or Beaker B (probe rinse), ml

C_{SO_4} = concentration of sulfate in filter or probe rinse solution aliquots, mg/liter

Equations--

$$FP(mg) = \text{gross weight Beaker A} - \text{tare weight Beaker A} - \text{filter tare weight} \quad \text{Eq. 1}$$

$$PRP(mg) = \text{gross weight Beaker B} - \text{tare weight Beaker B} \quad \text{Eq. 2}$$

$$AS(mg) = C_{SO_4}\ (mg/liter) \times V_{evap}\ (ml) \times \frac{liter}{1000\ ml} \times 1.376\ \left(\frac{mg\ AS}{mg\ SO_4}\right) \quad \text{Eq. 3}$$

Mass of Nonwater-Soluble Sulfate Particulate

The sum of the particulate** collected on the filter (FP) and the particulate* collected in the probe rinse (PRP) is equal to the sum of nonwater-soluble sulfate particulate (NWSSP) and ammonium sulfate (AS) in both samples:

$$FP + PRP = NWSSP + AS_f + AS_{pr} \quad \text{Eq. 4}$$

The NWSSP can be found be rearranging the equation and substituting appropriate values determined using Equations 1, 2, and 3.

$$NWSSP = FP + PRP - AS_f - AS_{pr} \quad \text{Eq. 5}$$

*Particulate excluding water-soluble sulfates.

**Particulate with H_2SO_4 converted to $(NH_4)_2SO_4$.

Sulfuric Acid Mist Analysis

The volume of the sample solution was recorded and the pH of the sample determined. The sample volume was diluted to 500 ml with 80 percent IPA. A 100 ml aliquot of this solution was pipetted into a 250 ml Erlenmeyer flask with 2 to 3 drops of thorin indicator and titrated to a pink end point using 0.0100 N barium perchlorate. If the end point color was not correct, the sample was passed through an ion exchange resin and retitrated. A blank was titrated for each sample in the same manner.

Sulfur Dioxide Analysis

The sample was diluted to 500 ml with deionized, distilled water. A 20 ml aliquot of this solution was pipetted into a 250 Erlenmeyer flask with 80 ml of 100 percent IPA and 2 to 3 drops thorin indicator. The solution was then titrated to a pink end point using 0.0100 N barium perchlorate. A blank was titrated in the same manner.

APPENDIX E

CALIBRATION PROCEDURES AND RESULTS

CALIBRATION PROCEDURES AND RESULTS

All of the equipment used was calibrated according to the procedures outlined in Maintenance, Calibration, and Operation of Isokinetic Source-Sampling Equipment.*

NOZZLE DIAMETER

The nozzles were calibrated by making three separate measurements using different inside diameters and calculating the average. If a deviation of more than 0.004 inches was found the nozzle was either discarded or reamed out and remeasured. A micrometer was used for measuring. These calibration data are shown in Figures E-1a and b.

PITOT TUBE CALIBRATION

The pitot tubes used in sampling were constructed by PEDCo Environmental and met all requirements of Method 2, Section 4.1 of the Federal Register.** Therefore, a baseline coefficient of 0.84 was assigned to each pitot tube. See Figures E-2 and E-3 for alignment requirements of Method 2, and Figures E-4a and b for actual inspection data of the pitot tubes used during the test program.

DRY GAS METER AND ORIFICE METER

Figure E-5 was the set-up used for the initial and post-test calibration. A wet test meter with a 2-cubic-feet-per-minute capacity and ±1 percent accuracy was used. The pump was run for approximately 15 minutes at an orifice manometer setting of 0.5 inch of water to heat up the pump and wet the interior surface of the wet test meter. The information on Figure E-6 (example calculation sheet) was gathered for the initial calibration and then, the ratio of accuracy of the wet test meter to the dry test meter, and the ΔH@ were calculated.

POST-TEST METER CALIBRATION CHECK

A post-test meter calibration check was made on the meter box used during the test to check its accuracy against its last calibration check. This post-test calibration must be within ±5 percent of the initial calibration. The initial calibration was performed as described in APTD-0576. The post-test calibration was performed using the same method as the initial calibration. Three calibration runs were made using the average orifice setting obtained during each test run and with the vacuum set at the average value obtained during each test run. After running the post-test calibration check all three runs were within the ±5 percent range allowed by the Federal Register.*

The initial and post-test meter box calibration data are presented in Figures E-7a through h.

Figure E-7h. Particulate sampling meter box post-test calibration.

THERMOCOUPLES

Thermocouples were calibrated by comparison against an ASTM-2F thermometer at approximately 32°F, ambient temperature, 100°F, and 500°F. The thermocouples read within 1.5 percent of the reference thermometer throughout the entire range when expressed in degrees Rankine. If a thermocouple did not read within 1.5 percent, a correction formula based on a least squares analysis of the data was utilized. The correction formula corrected the data to within 1.5 percent. Each thermocouple was checked at ambient temperature at the test site to verify the calibration. Calibration data are presented in Figures E-8a and b.

DIGITAL INDICATOR FOR THERMOCOUPLE READOUT

A digital indicator was calibrated by feeding a series of millivolt signals to the input, and comparing the indicator reading with the reading the signal should have generated. Error did not exceed 0.5 percent when the temperatures were expressed in degrees Rankine. Calibration data are shown in Figures E-9a and b.

DRY GAS THERMOMETERS

The dry gas thermometers were calibrated by comparison against an ASTM-2F thermometer at approximately 32°F, at ambient temperature, and at approximately 110°F. The thermometers agreed within 5°F of the reference thermometer. The impinger thermometers were calibrated by comparison against ASTM-2F thermometer at approximately 32°F and ambient temperature. Calibration data are included in Figures E-10a through d and E-11a through d.

BALANCE

The Mettler electronic balance was calibrated by comparison with Class-S standard weights and agreed within 0.5 g. Calibration data are shown in Figure E-12.

BAROMETER

The field barometer was calibrated to within 0.1 in.Hg of an NBS-traceable mercury-in-glass barometer before each test series. The field barometer was checked against the mercury-in-glass barometer after each test series to determine if it read within 0.2 in.Hg. If it did not reading within 0.2 in.Hg, a correction factor was determined. Calibration data are included in Figure E-13.

ORSAT ANALYZER

The orsat analyzer was calibrated before each test series by determining the percentages of carbon dioxide and oxygen in a calibration gas containing known percentages of each. The analyzer read within 0.5 percent of the known value for each gas. Calibration data are shown in Figures E-14a through c.

Balance No.	Date	Calibrator	Mass determined for					
			~~5~~ 200 g	Error	~~50~~ 500 g	Error	~~100~~ 1000 g	Error
M-1*	12/7/82	D. Osterkamp	200.1	+0.1	500.2	+0.2	1000.4	+0.4
M-1*	2/7/83	D. Schaffel	199.8	-0.2	499.5	-0.5	~~50~~ 49.9	-0.1

Error must not exceed 0.5 grams at each point.

*Balance was also calibrated by manufacturer on 10/6/82.

APPENDIX F

QUALITY ASSURANCE SUMMARY

QUALITY ASSURANCE

The following summary addresses the general steps taken to insure data quality and accuracy for any given emission test project.

PROJECT ORGANIZATION AND RESPONSIBILITIES

The project organization and responsibilities of the project team are generally defined in the test plan. Specific responsibilities for this field test are shown in Appendix G, Project Participants.

QUALITY ASSURANCE OBJECTIVE

The primary objective of this program is to refine sampling and analytical techniques of EPA Proposed Method 5B (or develop a new method) that will minimize the collection of condensible sulfate materials in the measurement of particulate emissions from fossil fuel-fired boilers and to evaluate method precision. Therefore, all procedures used in the collection and analysis of emission samples were as outlined in applicable EPA reference methods, where applicable. The sample methodology used for this project (quad train - single point) has been previously validated specifically for research and methods development type projects.

Test results were presented in several units to allow for their comparison with data from other organizations wishing access to the data summary.

DATA REDUCTION, VALIDATION, AND REPORTING

Data reduction and reporting provide one of the greatest potential sources of system error. To help minimize this source of error, PEDCo performs most test method calculations by use of a validated computer program. In addition, hand calculation on standard computer cards to allow accurate input of data into the computer by individuals unfamiliar with testing procedures. The data printout is then validated by comparison with the field and analytical data sheets. In addition, hand calculation checks generally are made to validate the computer output. Other data validations are made whenever possible.

PERFORMANCE AND SYSTEM AUDITS AND FREQUENCY

When feasible, PEDCo performs both performance and system audits. Three types of performance audits were performed for this test program. All dry gas meter systems were audited for accuracy in the field by the use of a critical orifice. In addition, the analytical procedure for sulfur dioxide was audited for accuracy by the use of audit samples supplied by EPA prior to sample analysis. Also, onsite calculations were used to check the completeness and accuracy of the particulate test data.

The PEDCo Project Director was on-site February 11 and performed a general system audit as an internal evaluation of

sampling personnel and equipment. The EMB Task Manager was also on-site during the major portion of the test series and performed a separate system audit.

SPECIFIC ROUTINE PROCEDURES USED TO ASSESS DATA PRECISION, ACCURACY, AND COMPLETENESS

Because the precision of the standard EPA reference methods used had previously been determined, no further attempt was made to assess data precision. These precision results are summarized in "The EPA Program for the Standardization of Stationary Source Emission Test Methodology, A Review," EPA-600/4-76-044. Precision estimates were calculated for within-run M5B and M5B-P400 samples using standard statistical analysis procedures. The mean concentration and standard deviation (with N-1 weightings for sample data) were determined for each group of similar runs. The standard deviations were expressed as a percentage of the mean concentration for comparison purposes (called the relative standard deviation).

Three audit procedures were used to determine accuracy. Accuracy audit procedures used for the dry gas meter and sulfur dioxide, analysis are the standardized written procedures used by the EPA Quality Assurance Division program. The procedure for determining data completeness is the same as that for New Source Performance Standards, as documented in the Code of Federal Registers 40 CFR 60, Section 60.8

INTERNAL QUALITY CONTROL CHECKS

Several internal quality control checks are usually made for each test. Normally, most of these checks deal with the field sampling analysis. For this test series, control samples for the sulfur dioxide analytical procedures were analyzed. Also, filter and reagent blanks were returned to the laboratory for gravimetric analysis. A quality control check of both the initial and final weighing was thus provided. Results of the control sample checks are included in Section 6. Blanks were analyzed according to procedures used for the M5BW and IC analytical work.

CORRECTIVE ACTION

PEDCo has two methods for corrective action. The first involves the use of control limits, such as audit sample results, control sample results, and calibration results. When any of these limits show that the integrity of the data is questionable the procedure is repeated, additional data are collected, or the data are rejected. The second method involves the use of red tags. Whenever any piece of equipment is suspected of producing unacceptable data, the entire apparatus or malfunctioning component is replaced and a red tag is placed on the item. That piece of equipment is then rejected until its ability to perform its function correctly is verified by the proper individuals. The use of numerous control limits and the red tagging system reduces the amount of unacceptable data and provides a system by which to track and correct items and procedures that show an unusally high occurrence of unacceptability.

PREVENTIVE MAINTENANCE PROCEDURES AND SCHEDULES

PEDCo has a very comprehensive preventive maintenance program. Many of the major components of test equipment have pretest checklists. These checklists ensure that all functions are checked and action is taken to repair or replace any part that shows probability of malfunction. The checks are made before every field test series, however, only the control console (meter box) check are recorded. Even though PEDCo's preventive maintenance program and schedule are not in writing, our commitment of three full-time experienced persons for the express purpose of equipment construction, preparation, calibration, and maintenance has created a program based on experience and skill that cannot be matched by a written guideline.

QUALITY ASSURANCE REPORTS TO MANAGEMENT

The standard quality assurance procedures used in this test program generated sufficient documentation to indicate the data quality. All evidence of the execution of the quality assurance guidelines is reviewed by management. In addition, during weekly meetings of all PEDCo's EMB task managers and project managers, all aspects of the project are discussed including the quality assurance of each task. No written report results from this meeting because all interested parties are verbally apprised of the situation during each meeting.

Two other reports are made to managements, which are not EMB task related. PEDCo's emission test and laboratory groups participants in all national audits by EPA's Quality Assurance Division, and PEDCo's quality assurance coordinator, Tom Wagner, makes several independent checks for management.

APPENDIX G

PROJECT PARTICIPANTS AND SAMPLE LOG

TABLE G-1. FIELD TEST CREW AND RESPONSIBILITIES

Name	Title	Field test assignment
J. Prohaska	Project Manager	Coordinate test activity; sample train setup and disassembly
P. Clarke	Engineer	Site leader; particulate tests meter reader quad train
P. Reinermann	Engineer	Particulate tests meter reader quad train
R. Antesberger	Technician	Assist at sample site; quad train assembly and disassembly
D. Osterhout	Engineer	Site leader; clean up area; setup and recover sample trains
D. Scheffel	Technician	Setup and recover sample trains; Orsat analysis
W. DeWees	Project Director	System audit
G. McAlister	EPA Task Manager	Monitor test performance
J. Sellers	Plant contact	Coordinate plant activities; provide general on-site assistance; record process data
A. Kasprik	Company contact	Project coordination

TABLE G-2. SAMPLE LOG

Date (1983)	Activities
February 5-6	Sample site and equipment setup. All initial measurements were obtained. Sample recovery and setup area organized.
February 7-8	Two test runs were performed daily.
February 9-10	No tests were performed. Boiler operated at reduced load because of malfunctioning condensate pump.
February 11	Four test runs were performed. System audit conducted.
February 12	Two test runs were performed. Packed equipment and left site.

15. SUPPLEMENTARY NOTES

16. ABSTRACT

This report describes the development and evaluation of Method 5B at an oil-fired boiler. Different sampling and analysis techniques for measuring nonsulfuric acid particulate matter were compared and evaluated. Statistical analyses of the results comparing the precision of the different techniques are presented.
